                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    The present sequence is a gene encoding human alpha2B-adrenoceptor (alpha2B-AR) variant protein. Alpha2B-AR has a glutamic acid repeat celement (amino acids 298-309) of 12 glutamates, in an acidic stretch of 18 amino acids (amino acids 294-311), located in the third intracellular 1900 of the receptor polypeptide. The variant is obtained by deletion of 1900 celement is located on chromosome 2. Alpha2-AR mediate many of the 1900 celement is located on chromosome 2. Alpha2-AR mediate many of the 1900 celement is located on chromosome 2. Alpha2-AR mediate many of the 1900 celement is located on chromosome 2. Alpha2-AR mediate many of the 1900 celement in 1900 celem

                                                                                                                                                                                                                                                                                                                                                                                             S
                                                                                                                                                                                                                                                                                                                                                                                                                                    The invention relates to genotyping an alpha-2B, 2A, or 2C adrenergic CC receptor gene (I)-(III) by detecting a polymorphic site, comprising; CC (a) obtaining a sample having a polymorphic site, comprising; CC (a) postaining a sample having a polymorphic site comprising complement of; and CC (b) detecting a polymorphic site comprising nucleotide positions 901-909 CC of (I), a site comprising (A) (ggggggggcg) or (B) (gggggggtggg) at CC positions 961-972 of (III). The method may be used for genotyping an CC positions 961-972 of (III). The method may be used for genotyping an CC alpha2B, alpha2A or alpha2C receptor gene and further used to determine CC whether an individual is at increased risk of developing a disease CC second complete which correlate to disease selected from cardiovascular CC disease, central nervous system disease selected from cardiovascular CC disease, central nervous system disease selected from cardiovascular CC disease, central nervous system disease and combinations of these. In CC combinations of these, or alpha2C agonist (e.g. epinephrine, clonidine, oxymetazoline, guanabenz, UK14304, BHT933 and CC combinations of these) or antagonist (e.g. yohimbine, prazosin, ARC 239, CC rauwolscine, idazoxan, tolazoline, guanabenz, UK14304, BHT933 and CC combinations of the polymorphic site and correlating the site to a predetermined response (where the response is correlated to adenylyl CC cyclase, MAP kinase activity, phosphorylation or inosito phosphate CC (Aligogos). The polymorphic site and correlated to adenylyl CC cyclase, MAP present sequence is that of the third intracellular loop of the human alpha-2BAR variant, the sequence is deleted for a 9 nucleotide CC (Aligogos).
                                                                                                                                                                                                                                                                                                                    Query Match

                                                                                                                                                                                                                                                                                                                                                                                                                The invention relates to a method for detecting a risk of hypertension by determining the pattern of alleles encoding a variant alpha-2B-adrenoceptor (AR) potein. The methods and compositions of the invention are useful for detecting risks and targeting treatment for hypertension. The kit is also useful for selecting for clinical drug trials testing the antihypertensive effect of compounds. The present sequence is human
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Detecting a risk of hypertension and targeting treatment
by determining the pattern of alleles encoding a variant

                                                                                                                                                                                  Human alpha-2BAR third intracellular loop encoding
                                                                                                                                                                                                                                                                                                                                                                                                                                                  The present sequence is a gene encoding human alpha2B-adrenoceptor (alpha2B-AR) protein. Alpha2B-AR has a glittamic acid repeat element (amino acids 298-309) of 12 glutamates, in an acidic stretch of 18 amino the receptor polypeptide. Alpha2B-AR gene is located on chromosome 2. Alpha2-AR mediate many of the physiological effects of the catecholamines, norepinephrine and epinephrine. An antagonist of vascular contraction of coronary arteries and a disease involving as coronary heat disease (CHD), unstable chronic angina pectoris which is clinically expressed as Prinzmetal's variant form or acute myocardial infarction (AMI). Alpha2B-AR gene is used in gene therapy.
                                                                                                                                                                                                                                                                    AAI99905 standard; DNA;

CC The invention relates to genotyping an alpha-2B, 2A, or 2C adrenergic CC (a) obtaining a sample having a polymorphic site, comprising; CC (a) obtaining a sample having a polymorphic seconding an alpha-2B, CC (b) detecting a polymorphic site comprising mucleotide positions 901-909 (CC of (I)), a site comprising cytosine or guanine at position 753 of (IIV) (CC or a site comprising (A) (939309390ccg) or (B) (93939393ccg) at CC alpha2B, alpha2A or alpha2C receptor gene and further used to determine CC alpha2B, alpha2A or alpha2C receptor gene and further used to determine CC whether an individual is at increased risk of developing at a disease control site which correlate to disease selected from cardiovascular CC disease, central nervous system disease and combinations of these. In CC disease, central nervous system disease and combinations of these. In CC combinations of these) or antagonist (e.g. epinephrine, clonidine, oxymetazoline, guanabenz, UK14304, BHT933 and CC rauwolscine, idazoxan, tolazoline, phantolamine and combinations of combinations of these) by detecting the polymorphic site and correlating the site to a CC cyclase, MAP kinase activity, phosphorylation or inositol phosphate CC cyclase, MAP kinase activity, phosphorylation or inositol phosphate CC alpha-2BAR (GenBank Accession AF009500), the sequence includes CC alpha-2BAR variant (AA199906).

                                                                                                                                                                                                                                                                                                                                                                                                          The invention relates to a method for detecting a risk of hypertension by determining the pattern of alleles encoding a variant alpha-2B-adrenoceptor (AR) protein. The methods and compositions of the invention are useful for detecting risks and targeting treatment for hypertension. The kit is also useful for selecting for clinical drug trials testing

```
CC polynicleotide probes comprising a sequence selected from one of the 1490 CC sequences mentioned in the specification. The combination is useful as an CC array element in a microarray for monitoring the expression of a number of target polynicleotides. The microarray is particularly useful in the CC diagnosis and treatment of cancer and immunopathology and neuropathology. CC The microarray is useful in diagnostics and carcinogenicity studies, the convery and development, toxicological and carcinogenicity studies, CC forensics and pharmacogenomics. The microarray is also useful for CC monitoring progression of diseases and for developing sophisticated CC profiles for the effects of currently available therapeutic drugs. The CC combination is also useful for purifying a subpopulation of mRNAs, cDNAs and genomic fragments and in research and diagnostic applications. The CC combination is also useful for purifying a subpopulation of genes coding CC array can detect changes in expression in a large number of genes coding CC various diseases including cancer e.g. adenocarcinoma and leukaemia, concertion constitues of seases including cancer e.g. adenocarcinoma and leukaemia, concertion of probe of the invention of the present sequence represents a polynucleotide considered of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                WPI;

                                                                                                                                                                                                                                                                                                                                                         Ś
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 The present invention describes antigenic peptides (1) comprising:

(2) (a) any one of 1601 sequences (see ABP82019 to ABP83619) of 12-24 amino code and (2) an isolated antibody having high specificity and high affinity compared therapy. The antigenic peptides for GPCRs or a candidate polypeptide in a sample; compared therapy. The antigenic peptides for GPCRs are useful in detecting compressions and antibodies. The peptides and antibodies are also useful for detecting the GPCRs and antibodies are useful for detecting the CC gresence or absence of corresponding GPCRs. The antigenic peptides for GPCRs and designing drugs for creating immune-related diseases, growth-related designing drugs for creating immune-related diseases, growth-related designing drugs for cregeneration-related diseases, growth-related cell proliferative compared to a lerge of corresponding cal-related cell proliferative compared to a lerge of corresponding cal-related cell proliferative confidences, bacterial, fungal, protozoan or viral infections, corresponding cal-related cell proliferative corresponding protozoan or viral infections, corresponding cal-related cell proliferative corresponding cal-related cell proliferative corresponding protozoan or viral infections, corresponding cal-related cell proliferative call proliferative call proliferation, carried call proliferative call proliferative call proliferative call pro

                                                                                                                                                                                                                                                                                                                                                                                                 The present invention provides a number of human immune system associated genes which are modified by the methylation of cytosines. The sequences can be used in the diagnosis and treatment of immune system disorders, macular degeneration, arteriosclerosis, anaemia, cancer, sacute myeloid leukaemia, Alzheimer's disease, AIDS, epilepsy, neurofibromatosis, rheumatoid arthritis, psoriasis and inflammatory/ulcerative bowel diseases. The present sequence is a gene of the invention.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The invention relates to nucleic acids comprising a segment of chemically pretreated DNA of adrenergic alpha-1C-receptor gene. The invention also relates to oligonucleotides or peptide nucleic acid (PNA) oligomers useful for detecting cytosine methylations. The pretreated DNA is useful for the diagnosis or therapy of behavioural disorders, neurological disorders and cancer, in particular major depressive disorder, Tourette's syndrome, schizophrenia, psychiatric and neurological disorders, smoking, drug abuse, alcoholism, personallty traits, compulsive gambling, human immunodeficiency virus dementia, migraine, behaviours in schizophrenic and schizophrenia. The nucleic acid is useful for detecting the methylation state of all CpG dinucleotides and/or single nucleotide polymorphisms (SNPs). The present sequence is human chemically treated genomic DNA.

disease, central nervous system disease and combinations of these. In addition, the technique may be used to predict an individual's response to an alpha2B, alpha2A, or alpha2C agonist (e.g. epinephrine, clonidine, oxymetazoline, guanabenz, UK14304, BHT933 and combinations of these) or antagonist (e.g. yohimbine, prazosin, ARC 239, rauwolscine, idazoxan, tolazoline, phentolamine and combinations of these) by detecting the polymorphic shand correlating the site to a predetermined response (where the response is correlated to adenylyl cyclase, MAP kinase activity, phosphorylation or inositol phosphate levels). The present sequence is that of the human alpha-2AAR gene
                                                                                                                                                                                                                                                                                                             The invention relates to genotyping an alpha-2B, 2A, or 2C adrenergic receptor gene (I)-(III) by detecting a polymorphic site, comprising; (a) obtaining a sample having a polymorphic site, comprising; (a) obtaining a sample having a polymorphic site comprising an alpha-2B, alpha2A or alpha2C or fragment or complement of; and (b) detecting a polymorphic site comprising nucleotide positions 901-909 of (I), a site comprising cytosine or guanine at position 753 of (IIV) or a site comprising (A) (ggggggggcg) or (B) (gggggggtgg) at positions 961-972 of (III). The method may be used for genotyping an alpha2B, alpha2A or alpha2C are and further used to determine whether an individual is at increased risk of developing a disease associated with alpha2B, alpha2A or alpha2, comprising detecting a polymorphic site which correlate to disease selected from cardiovascular disease and combinations of these In
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Genotyping an alpha-2B, 2A, or 2C adrenergic receptor gene useful determining whether an individual is at increased risk of developi disease associated with the corresponding receptor comprises detec a polymorphic site -

methylation of a particular cytosine in a motif 5'-CpG-3', present in a cytosine (c) genomic sample of DNA. The sample is treated chemically to convert CC cytosine (c) but not methylated C, to uracil, then part of the genomic CC The amplicon is hybridised to two classes, each with at least one CC member, of oligonucleotides and/or peptide-nucleic acid (PNA) oligomers CC and the degree of hybridisation to both classes is determined from the CC lasses of oligomers, the degree of methylation is calculated. The method CC is used: (i) for diagnosis and/or prognosis of side effects of the central nervous, cardiovascular, gastrointestinal and respiratory CC of the central nervous, cardiovascular, gastrointestinal and respiratory CC polymorphisms (SNP's), and (ii) for differentiation or single nucleotide types and for investigating cell differentiation. The method allows the CC methylation status of many C residues to be determined simultaneously. CC method for determining the degree of cytosine methylation described in XX c.

Oligonucleotide for detecting cytosine methylation SEQ ID NO

Human; cytosine methylation; 5'-CpG-3'; uracil; cytosine; diagnosis; drug; side effect; cancer; central nervous system; cardiovascular; gastrointestinal; respiratory system; single nucleotide polymorphism SNP; cell differentiation; ds.

WO200218632-A2.

Homo sapiens.

```
This invention describes a novel method for determining the degree of CC methylation of a particular cytosine in a motif 5'-CpG-3', present in a CC genomic sample of DNA. The sample is treated chemically to convert CC cytosine (C) but not methylated C, to uracil, then part of the genomic CC DNA that contains the target C is amplified to form a labeled amplicon. CC The amplicon is hybridised to two classes, each with at least one CC member, of oligonuclectides and/or peptide-nucleic acid (PNA) oligomers CC and the degree of hybridisation to both classes is determined from the CC label on the amplicon. From the ratio of labels hybridised to the two CC classes of oligomers, the degree of methylation is calculated. The method is used: (1) for diagnosis and/or prognosis of side effects of the central nervous, cardiovascular, gastrointestinal and respiratory contents etc., particularly by detecting mutations or single nucleotide polymorphisms (SNP's); and (ii) for differentiation. The method allows the methylation status of many C residues to be determined simultaneously. ABQ13410-ABQ54121 represent genomic DNA sequences used to illustrate the method disclosure of the invention.
